

It converts fragmented official bulletins and citizen reports into one continuously updated, trustworthy incident feed

Users can submit voice, text or images in their preferred Indian language. Each claim is translated, time- and location-matched, compared with authoritative sources, checked for duplicate or recycled content, and grouped under the relevant real-world incident.

Instead of a vague “true/false” verdict, SatyaSetu displays a clear status—Officially Verified, Corroborated, Unverified, Misleading or Outdated—along with source, evidence, timestamp, expiry and confidence explanation. Alerts are prioritized by severity and proximity, then communicated through simple text, voice and visual instructions suitable for low-literacy and accessibility needs.

During weak connectivity, the platform preserves the latest verified safety guidance, queues reports for later synchronization and creates compact, shareable alert cards that retain provenance even when forwarded. Authorities receive a live map of clustered incidents, emerging rumours, resource requests and unresolved high-risk claims, with controls to verify, correct, update or expire information.

Disasters create an information crisis alongside the physical crisis. Official alerts, eyewitness reports, old photographs, mistranslations and deliberate rumours circulate together across social media and messaging groups. Citizens often cannot determine who issued a claim, whether it is current, whether it applies to their location or whether several posts describe the same incident. Duplicate reports can exaggerate severity, while contradictory instructions increase panic and delay safe action.

Language, literacy, disability and unreliable connectivity further prevent critical guidance from reaching vulnerable communities. At the same time, authorities and responders must manually examine large volumes of unstructured reports, wasting time and resources.

The platform must aggregate authoritative alerts, preserve provenance, understand multilingual and multimodal reports, merge duplicates, identify manipulated or contextually misleading content, and deliver location-relevant instructions quickly. It must visibly separate official information from community observations, explain uncertainty, protect sensitive user data and allow human authorities to review high-risk decisions. Both false rejection of a genuine emergency and false validation of a rumour can cause harm, so every alert must remain traceable, updateable and time-bound.

a Trust Passport for every emergency claim: a record of its issuer, evidence, location, timestamp, verification status, confidence reason and expiry. It appears on QR-linked shareable alert cards, helping users recognize outdated or altered information even after it is forwarded or screenshotted.

The platform also closes the correction loop. When a rumour is disproved or an alert changes, people who viewed, saved or shared it can receive the corrected version. Community reports can corroborate an incident through independent, nearby observations, but can never be presented as an official order without authorized approval.

Additional crisis-first features include voice and image reporting, read-aloud regional-language alerts, low-literacy visual instructions, geofenced relevance, offline safety packs, missing-person and resource-request consolidation, privacy-preserving location sharing, and an authority console for verification, expiry, broadcast corrections and audit trails. Together, these make SatyaSetu a transparent decision-support network rather than a black-box chatbot.

1. Significance of the problem statement.
2. Existing solution
3. Gap in the existing solution.
4. Existing approach
5. Potential Challenges and risks of our idea

- 1-Translates local news into desired language of person in text
- 2-Automatic group formation of affected people of a localised area
- 3-A dashboard that displays heat map of area affected as well as any info provided by government
- 4-Information can be sent through internet and fallback1 is SMS and Fallback2 is Bluetooth
- 5-Provides facility to chat with nearby affected people
- 6-Clearly verifies which news is fake and which is real
- 7-Supports multiple indian languages
- 8-Gives alerts of any Future weather disasters
- 9- People report who are injured and what kind of problems they are facing and message to community group
